~~Fig. 1V5 is a schematic representation of a presentation-type bar code symbol reading system embodying the PLIIM-based subsystem of Fig. 1V1;~~

**On Page 110,** amend the seventh paragraph as follows:

~~Figs. 18A and 18B~~ 18A, 18B-1 and 18B-2, taken together, set forth a real-time camera control process that is carried out within the camera control computer employed within the PLIIM-based systems of Fig. 11, wherein the camera control computer automatically processes the received time-stamped data sets and generates real-time camera control signals that drive the focus and zoom lens group translators within a high-speed auto-focus/auto-zoom digital camera subsystem (i.e. the IFD module) so that the camera subsystem automatically captures digital images having (1) square pixels (i.e. 1:1 aspect ratio) independent of package height or velocity,

(2) significantly reduced speckle-noise levels, and (3) constant image resolution measured in dots per inch (DPI) independent of package height or velocity;

**On Page 114, amend paragraph 4 as follows:**

~~Fig. 30 is~~ Figs. 30-1 through 30-4, taken together, set forth a schematic representation of the camera-based object identification and attribute acquisition subsystem of Fig. 27, illustrating the system architecture of the slave units in relation to the master unit, and that (1) the package height, width, and length coordinates data and velocity data elements (computed by the LDIP subsystem within the master unit) are produced by the master unit and defined with respect to the global coordinate reference system, and (2) these package dimension data elements are transmitted to each slave unit on the data communication network, converted into the package height, width, and length coordinates, and used to generate real-time camera control signals which intelligently drive the camera subsystem within each slave unit, and (3) the package identification data elements generated by any one of the slave units are automatically transmitted to the master slave unit for time-stamping, queuing, and processing to ensure accurate package dimension and identification data element linking operations in accordance with the principles of the present invention;

**On Page 115, amend paragraph 8 as follows:**

~~Fig. 33C is~~ Figs. 33C1 and 33C2, taken together, set forth a system block diagram illustrating the system architecture of the bioptical PLIIM-based product dimensioning, analysis and identification system of the first illustrative embodiment shown in Figs. 33A and 33B;

**On Page 137, amend paragraph 2 as follows:**

~~Fig. 68 is~~ Figs. 68-1 through 68-3, taken together, set forth a schematic block system diagram of a first illustrative embodiment of the airport security system of the present invention shown comprising (i) a passenger screening station or subsystem including PLIIM-based passenger facial and body profiling identification subsystem, hand-held PLIIM-based imagers,

and a data element linking and tracking computer, (ii) a baggage screening subsystem including PLIIM-based object identification and attribute acquisition subsystem, a x-ray scanning subsystem, and a neutron-beam explosive detection subsystems (EDS), (iii) a Passenger and Baggage Attribute Relational Database Management Subsystems (RDBMS) for storing co-indexed passenger identity and baggage attribute data elements (i.e. information files), and (iv) automated data processing subsystems for operating on co-indexed passenger and baggage data elements (i.e. information files) stored therein, for the purpose of detecting breaches of security during and after passengers and baggage are checked into an airport terminal system;

**On Page 138,** amend the second and third paragraphs as follows:

~~Fig. 69A is~~ Figs. 69A1 through 69A3 set forth a schematic block system diagram of a second illustrative embodiment of the airport security system of the present invention shown comprising (i) a passenger screening station or subsystem including PLIIM-based object identification and attribute acquisition subsystem, (ii) a baggage screening subsystem including PLIIM-based object identification and attribute acquisition subsystem, an RDID object identification subsystem, a x-ray scanning subsystem, and pulsed fast neutron analysis (PFNA) explosive detection subsystems (EDS), (iii) a internetworked passenger and baggage attribute relational database management subsystems (RDBMS), and (iv) automated data processing subsystems for operating on co-indexed passenger and baggage data elements stored therein, for the purpose of detecting breaches of security during and after passengers and baggage are checked into an airport terminal system;

Fig. 69B1 through 69B3, taken together, set forth a flow chart illustrating the steps involved in a second illustrative embodiment of the airport security method of the present invention carried out using the airport security system shown in ~~Fig. 69A~~ Figs. 69A1 through 69A3;

**On Page 217,** amend the first paragraph as follows:

In ~~Figs. 4H25C1~~ 1I25C1 and 1I25C2, there is shown a PLIIM-based system of the present invention 885 having speckle-pattern noise reduction capabilities embodied therein, which comprises: (i) an image formation and detection (IFD) module 861 mounted on an optical bench 862 and having a linear (1D) CCD image sensor 863 with vertically-elongated image detection elements 864 characterized by a large height-to-width (H/W) aspect ratio; (ii) a PLIA

comprising a pair of planar laser illumination modules (PLIMs) 865A and 865B mounted on the optical bench on opposite sides of the IFD module; and (iii) a 2-D PLIB micro-oscillation mechanism 886 arranged with each PLIM in an integrated manner.

**On Page 295, amend paragraphs 2, 3 and 5 as follows:**

As will be described in greater detail hereinafter, the camera control computer 22 controls the auto-focus/auto-zoom digital camera subsystem 3'' in an intelligent manner using the real-time camera control process illustrated in Figs. ~~18A and 18B~~ 18A, 18B-1 and 18B-2. A particularly important inventive feature of this camera process is that it only needs to operate on one data set at time a time, obtained from the LDIP Subsystem 122, in order to perform its complex array of functions. Referring to Figs. ~~18A and 18B~~ 18A, 18B-1 and 18B-2, the real-time camera control process of the illustrative embodiment will now be described with reference to the data structures illustrated in Figs. 19 and 20, and the data tables illustrated in Figs. 21 and 23.

#### Real-Time Camera Control Process Of The Present Invention

In the illustrative embodiment, the Real-time Camera Control Process 560 illustrated in Figs. ~~18A and 18B~~ 18A, 18B-1 and 18B-2 is carried out within the camera control computer 21 of the PLIIM-based system 120 shown in Fig. 9. It is understood, however, that this control process can be carried out within any of the PLIIM-based systems disclosed herein, wherein there is a need to perform automated real-time object detection, dimensioning and identification operations.

As illustrated in Figs. ~~18A and 18B~~ 18A, 18B-1 and 18B-2, the camera control process of the present invention has multiple control threads that are carried out simultaneously during each data processing cycle (i.e. each time a new data set is received from the Real-Time Package Height Profiling And Edge Detection Processing Module 550 within the LDIP subsystem 122). As illustrated in this flow chart, the data elements contained in each received data set are automatically processed within the camera control computer in the manner described in the flow

chart, and at the end of each data set processing cycle, generates real-time camera control signals that drive the zoom and focus lens group translators powered by high-speed motors and quick-response linkage provided within high-speed auto-focus/auto-zoom digital camera subsystem (i.e. the IFD module) 3” so that the camera subsystem 3” automatically captures digital images having (1) square pixels (i.e. 1:1 aspect ratio) independent of package height or velocity, (2) significantly reduced speckle-noise levels, and (3) constant image resolution measured in dots per inch (DPI) independent of package height or velocity. Details of this control process will be described below.

**On Page 297, amend paragraph 7 as follows:**

At Block D in Fig. 18A, at this stage in the control process, the camera control computer 22 analyzes the height values (i.e. coordinates) buffered in the Package Data Buffer, and determines the current “median” height of the package. At this stage of the control process, numerous control “threads” are started, each carrying out a different set of control operations in the process. As indicated in the flow chart of Figs. ~~18A and 18B~~ 18A, 18B-1 and 18B-2, each control thread can only continue when the necessary parameters involved in its operation have been determined (e.g. computed), and thus the control process along a given control thread must wait until all involved parameters are available before resuming its ultimate operation (e.g. computation of a particular intermediate parameter, or generation of a particular control command), before ultimately returning to the start Block A, at which point the next time-stamped data set is received from the Real-Time Package Height Profiling And Edge Detection Processing Module 550. In the illustrative embodiment, such data set input operations are carried out every 5 milliseconds, and therefore updated camera commands are generated and provided to the auto-focus/auto-zoom camera subsystem at substantially the same rate, to achieve real-time adaptive camera control performance required by demanding imaging applications.

**On Page 298, amend paragraphs 1 and 6 as follows:**

As indicated at Blocks E, F, G H, I, A in Figs. ~~18A and 18B~~ 18A, 18B-1 and 18B-2, a first control thread runs from Block D to Block A so as to reposition the focus and zoom lens groups within the auto-focus/auto-zoom digital camera subsystem each time a new data set is received from the Real-Time Package Height Profiling And Edge Detection Processing Module 550.

As indicated at Blocks D, K, L, M in Figs. ~~18A and 18B~~ 18A, 18B-1 and 18B-2, a second control thread runs from Block D in order to determine and set the optimal photo-integration time period ( $\Delta T_{\text{photo-integration}}$ ) parameter which will ensure that digital images captured by the auto-focus/auto-zoom digital camera subsystem will have pixels of a square geometry (i.e. aspect ratio of 1:1) required by typical image-based bar code symbol decode processors and OCR processors. As indicated at Block K, the camera control computer analyzes the current median height value in the Data Package Buffer, and determines the speed of the package ( $V_b$ ). At Block L, the camera control computer uses the computed values of average (i.e. median) package height, belt speed and Photo-Integration Time Look-Up Table in Fig. 22B, to determine the photo-integration time parameter ( $\Delta T_{\text{photo-integration}}$ ) which will ensure that digital images captured by the auto-focus/auto-zoom digital camera subsystem will have pixels of a “square” geometry (i.e. aspect ratio of 1:1).

**On Page 299, amend paragraph 2 as follows:**

Reference will now be made to Fig. 18D and 18E1 and E2 in order to explain the camera line rate compensation operation of the present invention carried out at Block L in ~~Fig. 18B~~ Figs. 18B-1 and 18B-2. Notably, the primary purpose of this operation is to automatically compensate for viewing-angle distortion which would otherwise occur in images of object surfaces captured as the object surfaces move past the coplanar PLIB/FOV of PLIIM-based linear 25' at skewed viewing angles, defined by slope angles  $\theta$  and  $\phi$  in Figs. 18E1 and 18E2, for the cases of top scanning and side scanning, respectively.

**On Page 300, amend paragraphs 1 and 2 as follows:**

In a PLIIM-based linear imaging system, configured above a conveyor belt structure as shown in Fig. 18E1, the Line Rate of the linear image detection array in the camera subsystem will be dynamically adjusted in accordance with the principles of the present invention described above. In this case, the method employed at Block L in ~~Fig. 18B~~ Figs. 18B-1 and 18B-2 and detailed in Fig. 18D will provide a high level of compensation for viewing angle distortion presented when imaging (the plane of) a moving object surface disposed skewed at some slope angle  $\theta$  measured relative to the planar surface of the conveyor belt. In this case, the difficulty will should not reside in line-rate compensation, but rather in dynamically focusing the image formation optics of the camera (IFD) subsystem in response to the geometrical characteristics of the top surfaces of packages measured by the LDIP subsystem (i.e. instrument) 122 on a real-time basis. For example, during illumination and imaging operations, a slanted or sloped top surface of a transported box or object must remain in focus under the camera subsystem. To achieve such focusing, the slope of the object's top surface should be within a certain value, across the entire conveyor belt. However, in the top scanning case, if the box is rotated along the direction of travel so that the slope of the top surface thereof is not substantially the same across the conveyor belt (i.e. the height values of the box vary across the width of the conveyor belt), then it will be difficult for the camera subsystem to focus on the entire top surface of the box, across the width of the conveyor belt. In such instances, the LDIP subsystem 122 in system 120 has the option (at Block L in ~~Fig. 18B~~ Figs. 18B-1 and 18B-2) of providing only a single height value to the camera control computer 22 (e.g. the average value of the height values of the box measured across the conveyor belt), and for this average value to be used by the camera control computer 22 to adjustably control the camera's zoom and focus characteristics. Alternatively, the LDIP subsystem 122 can transmit to the camera control computer 22, data representative of the actual slope and shape of the top surface of the box, and such data can be used to control the focusing optics of the camera subsystem in a more complicated manner permitted by the image forming optics used in the linear PLIIM-based imaging system.

For the case of side scanning shown in Fig. 18E2, the method of the present invention employed at Block L in ~~Fig. 18B~~ Figs. 18B-1 and 18B-2 and detailed in Fig. 18D will provide a high level of compensation for viewing angle distortion which will otherwise occur in images of object surfaces when viewing (the plane of) the moving object surface disposed skewed at some angle  $\phi$  measured relative to the edge of the conveyor belt.

**On Page 301, amend paragraphs 1, 2, 4 and 5 as follows:**

Referring back now to Block M in ~~Fig. 18B~~ Figs. 18B-1 and 18B-2, it is noted that the camera control computer 22 generates a digital control signals for the parameters (1) Photo-integration Time Period ( $\Delta T_{\text{photo-integration}}$ ) found in the Photo-Integration Time Look-Up Table set forth in Fig. 1822B, and (2) the Compensated Line Rate parameter computed using the procedure set forth in Fig. 18D. Thereafter, the camera control computer 22 transmits these digital control signals to the CCD image detection array employed in the auto-focus/auto-zoom digital camera subsystem (i.e. the IFD Module). Thereafter, this control thread returns to Block A as indicated in Fig. 18A.

As indicated at Blocks D, N, O, P, R in ~~Figs. 18A and 18B~~ 18A, 18B-1 and 18B-2, a third control thread runs from Block D in order to determine the pixel indices (i,j) of a selected portion of a captured image which defines the “region of interest” (ROI) on a package bearing package identifying information (e.g. bar code label, textual information, graphics, etc.), and to use these pixel indices (i,j) to produce image cropping control commands which are sent to the image processing computer 21. In turn, these control commands are used by the image processing computer 21 to crop pixels in the ROI of captured images, transferred to image processing computer 21 for image-based bar code symbol decoding and/or OCR-based image processing. This ROI cropping function serves to selectively identify for image processing only those image pixels within the Camera Pixel Buffer of Fig. 20 having pixel indices (i,j) which spatially correspond to the (row, column) indices in the Package Data Buffer of Fig. 19.

At Block O in ~~Fig. 18B~~ Figs. 18B-1 and 18B-2, the camera control computer detects the x coordinates of the package boundaries based on the spatially transformed coordinate values of the left and right package edges (LPE,RPE) buffered in the Package Data Buffer, shown in Fig. 19.

At Block P in ~~Fig. 18B~~ Figs. 18B-1 and 18B-2, the camera control computer 22 determines the corresponding pixel indices (i,j) which specifies the portion of the image frame (i.e. a slice of the region of interest), to be effectively cropped from the image to be subsequently captured by the auto-focus/auto-zoom digital camera subsystem 3”. This pixel indices

specification operation involves using (i) the x coordinates of the detected package boundaries determined at Block O, and (ii) optionally, the subrange of x coordinates bounded within said detected package boundaries, over which maximum range “intensity” data variations have been detected by the module of Fig. 15. By using the x coordinate boundary information specified in item (i) above, the camera control computer 22 can determine which image pixels represent the overall detected package, whereas when using the x coordinate subrange information specified in item (ii) above, the camera control computer 22 can further determine which image pixels represent a bar code symbol label, hand-writing, typing, or other graphical indicia recorded on the surface of the detected package. Such additional information enables the camera control computer 22 to selectively crop only pixels representative of such information content, and inform the image processing computer 21 thereof, on a real-time scanline-by-scanline basis, thereby reducing the computational load on image processing computer 21 by use of such intelligent control operations.

**On Page 302, amend paragraphs 1 and 2 as follows:**

Thereafter, this control thread dwells at Block R in ~~Fig. 18B~~ Figs. 18B-1 and 18B-2 until the other control threads terminating at Block Q have been executed, providing the necessary information to complete the operation specified at Block Q, and then proceed to Block R, as shown in ~~Fig. 18B~~ Figs. 18B-1 and 18B-2.

As indicated at Block Q in ~~Fig. 18B~~ Figs. 18B-1 and 18B-2, the camera control computer uses the package time stamp ( $nT$ ) contained in the data set being currently processed by the camera control computer, as well as the package velocity ( $V_b$ ) determined at Block K, to determine the “Start Time” of Image Frame Capture (STIC). The reference time is established by the package time stamp ( $nT$ ). The Start Time when the image frame capture should begin is measured from the reference time, and is determined by (1) predetermining the distance  $\Delta z$  measured between (i) the local coordinate reference frame embedded in the LDIP subsystem and (ii) the local coordinate reference frame embedded within the auto-focus/auto-zoom camera subsystem, and dividing this predetermined (constant) distance measure by the package velocity ( $V_b$ ). Then at Block R, the camera control computer 22 (i) uses the Start Time of Image Frame Capture determined at Block Q to generate a command for starting image frame capture, and (ii)

uses the pixel indices (i,j) determined at Block P to generate commands for cropping the corresponding slice (i.e. section) of the region of interest in the image to be or being captured and buffered in the Image Buffer within the IFD Subsystem (i.e. auto-focus/auto-zoom digital camera subsystem).

**On Page 310, amend paragraph 2 as follows:**

As shown in Fig. 25, unitary system 140 comprises a PLIIM-based camera subsystem 25''' which includes a high-resolution 2D CCD camera subsystem 25'' similar in many ways to the subsystem shown in Figs. 6D1 through 6E3, except that the 2-D CCD camera's 3-D field of view is automatically steered over a large scanning field, as shown in Fig. 6E4, in response to FOV steering control signals automatically generated by the camera control computer 22 as a low-resolution CCD area-type camera (640x640 pixels) 61 determines the x,y position coordinates of bar code labels on scanned packages. As shown in Figs. 5B3, 5C3, 6B3, and 6C3, the components (61A, 61B and 62) associated with low-resolution CCD area-type camera 61 are easily integrated within the system architecture of PLIIM-based camera subsystems. In the illustrative embodiment, low-resolution camera 61 is controlled by a camera control process carried out within the camera control computer 22, by modifying the camera control process illustrated in Figs. ~~18A and 18B~~ 18A, 18B-1 and 18B-2. The major difference with this modified camera control process is that it will include subprocesses that generate FOV steering control signals, in addition to zoom and focus control signals, discussed in great detail hereinabove.

**On Page 315, amend paragraph 3 as follows:**

In this illustrative tunnel-type system, only the top PID unit 120 includes an LDIP subsystem 122 for object detection, tracking, velocity-detection and dimensioning/profiling functions, as this PID unit functions as a master PID unit within the tunnel system 570, whereas the side and bottom PID units 120 are not provided with a LDIP subsystem 122 and function as slave PID units. As such, the side and bottom PID units 120' are programmed to receive object dimension data (e.g. height, length and width coordinates) from the master PID unit 120 on a real-time basis, and automatically convert (i.e. transform) these object dimension coordinates

into their local coordinate reference frames in order to use the same to dynamically control the zoom and focus parameters of the camera subsystems employed in the tunnel system. This centralized method of object dimensioning offers numerous advantages over prior art systems and will be described in greater detail with reference to Figs. ~~30~~ 30-1 through 32B.

**On Page 316, amend paragraphs 1-3 as follows:**

In Figs. ~~30~~ 30-1 through 32B, CCD camera-based tunnel system 570 of Fig. 27 is schematically illustrated employing a real-time method of automatic camera zoom and focus control in accordance with the principles of the present invention. As will be described in greater detail below, this real-time method is driven by object coordinate data and involves (i) dimensioning packages in a global coordinate reference system, (ii) producing object (e.g. package) coordinate data referenced to said global coordinate reference system, and (iii) distributing said object coordinate data to local coordinate references frames in the system for conversion of said object coordinate data to local coordinate reference frames and subsequent use automatic camera zoom and focus control operations upon said packages. This method of the present invention will now be described in greater detail below using the four-sided tunnel-based system 570 of Fig. 27, described above.

As shown in ~~Fig. 30~~ Figs. 30-1 through 30-4, the four-sided tunnel-type camera-based object identification and attribute acquisition system of Fig. 27 comprises: a single master PID unit 120 embodying a LDIP subsystem 122, mounted above the conveyor belt structure 571; three slave PID units 120', 120' and 120', mounted on the sides and bottom of the conveyor belt; and a high-speed data communications network 572 supporting a network protocol such as, for example, Ethernet protocol, and enabling high-speed packet-type data communications among the four PID units within the system. As shown, each PID unit is connected to the network communication medium of the network through its network controller 132 (133) in a manner well known in the computer networking arts.

As schematically illustrated in Figs. ~~30 and~~ 30-1 through 31, local coordinate reference systems are symbolically embodied within each of the PID units deployed in the tunnel-type system of Fig. 27, namely: local coordinate reference system  $R_{local0}$  symbolically embodied within the master PID unit 120; local coordinate reference system  $R_{local1}$  symbolically embodied

within the first side PID unit 120'; local coordinate reference system  $R_{local2}$  symbolically embodied within the second side PID unit 120'; and local coordinate reference system  $R_{local3}$  symbolically embodied within the bottom PID unit 120'. In turn, each of these local coordinate reference systems is "referenced" with respect to a global coordinate reference system  $R_{global}$  symbolically embodied within the conveyor belt structure. Object coordinate information specified (by vectors) in the global coordinate reference system can be readily converted to object coordinate information specified in any local coordinate reference system by way of a homogeneous transformation (HG) constructed for the global and the particular local coordinate reference system. Each homogeneous transformation can be constructed by specifying the point of origin and orientation of the x,y,z axes of the local coordinate reference system with respect to the point of origin and orientation of the x,y,z axes of the global coordinate reference system. Such details on homogeneous transformations are well known in the art.

**On Page 318**, amend paragraph 2 as follows:

In addition, ~~Fig. 30~~ Figs. 30-1 through 30-4 illustrates that the LDIP subsystem 122 within the master unit 120 generates (i) package height, width, and length coordinate data and (ii) velocity data, referenced with respect to the global coordinate reference system  $R_{global}$ . These package dimension data elements are transmitted to each slave PID unit 120' on the data communication network, and once received, its camera control computer 22 converts ~~there~~ their values into package height, width, and length coordinates referenced to its local coordinate reference system using its preprogrammable homogeneous transformation. The camera control computer 22 in each slave PID unit 120 uses the converted object dimension coordinates to generate real-time camera control signals which automatically drive its camera's automatic zoom and focus imaging optics in an intelligent, real-time manner in accordance with the principles of the present invention. The "object identification" data elements generated by the slave PID unit are automatically transmitted to the master PID unit 120 for time-stamping, queuing, and processing to ensure accurate object identity and object attribute (e.g. dimension/profile) data element linking operations in accordance with the principles of the present invention.

**On Page 403**, amend the sixth and seventh paragraphs as follows:

In Figs. ~~69A and 69A1 through~~ 69B, there is shown a second illustrative embodiment of the novel airport security system of the present invention, indicated by reference numeral 2690.

As shown in ~~Fig. 69A~~ Figs. 69A1 through 69A3, the second illustrative embodiment of the airport security system 2690 comprises a number of primary system components, namely: (i) a Passenger Screening Station or Subsystem 2631; (ii) a Baggage Screening Station or Subsystem 2691; (iii) a Passenger And Baggage Attribute Relational Database Management Subsystems (RDBMS) 2633; and (iv) one or more Automated Data Processing Subsystems 2633 for operating on co-indexed passenger and baggage data captured by subsystems 2631 and 2691 and stored in the Passenger and Baggage Attribute RDBMS 2633, in order to detect possible breaches of security during and after the screening of passengers and baggage within an airport or like terminal system.

**On Page 404, amend all paragraphs as follows:**

As shown in ~~Fig. 69A~~ Figs. 69A1 through 69A3, the passenger screening subsystem 2631 comprises: (1) a PID/BID bar code symbol dispensing subsystem 2635 for dispensing a passenger identification (PID) bar code symbols and baggage identification (BID) bar code symbols to passengers; (2) a smart-type passenger identification card reader 2675 for reading a smart ID card 2676 having an IC chip supported thereon, as well as a magstripe, and a 2-D bar code symbol (e.g. commercially available from ActivCard, Inc., <http://www.activcard.com>); (3) a passenger face and body profiling and identification subsystem (i.e. 3-D digitizer) 2645; (4) one or more hand-held PLIIM-based imagers 2636; (5) a retinal (and/or iris) scanner 2637 and/or other biometric scanner 2638; and (6) a data element linking and tracking computer 2639. The information produced by subsystems, 122,120, 2637, and 2638 is considered to be "passenger attribute" type data elements. Passenger screening station 2631 may also include a TDS integrated into the system.

As shown in ~~Fig. 69A~~ Figs. 69A1 through 69A3, the PID/BID bar code symbol dispensing subsystem 2635 is installed at a passenger check-in or screening station, for the purpose of dispensing (i) a unique PID bar code symbol 2640 and bracelet 2641 to be worn by each passenger checking into the airport system, and (ii) a unique BID bar code label 2642 for attachment to each article of baggage to be carried aboard the aircraft on which the checked-in passenger will fly (or on another aircraft). Each BID bar code symbol 2642 assigned to a baggage article is co-indexed with the PID bar code symbol 2640 assigned to the passenger checking the article of baggage.

As shown in ~~Fig. 69A~~ Figs. 69A1 through 69A3, the passenger face and body profiling and identification subsystem 2645, can be realized by a PLIIM subsystem 25, for capturing a digital image of the face, head and upper body of each passenger to board an aircraft at the airport, or by a LDIP subsystem 122 as a 3-D laser scanning digitizer for capturing a digital 3-D profile of the passenger's face and head (and possibly entire body).

As shown in ~~Fig. 69A~~ Figs. 69A1 through 69A3, the baggage screening station 2691 comprises: an X-radiation baggage scanning subsystem 2650; a conveyor belt structure 2651; and a package identification and attribute acquisition system 120A and an RDIF-tag based object identification device 2693 mounted above the conveyor belt structure 2651, before the entry port of the X-radiation baggage scanning subsystem 2650 (or physically and electrically integrated therein), for automatically performing the following set of functions: (i) identifying each article of baggage 2643 by reading the baggage identification (BID) bar code symbol 2642 applied thereto at the baggage screening station 2691; (ii) dimensioning (i.e. profiling) the article of baggage and generating baggage profile information; (iii) capturing a digital image of the article of baggage; (iv) indexing such baggage attribute data with the corresponding BID number encoded either into the scanned BID-encoded bar code symbol or the scanned BID-encoded RFID-tag applied to each article of baggage; and (v) sending such BID-indexed baggage attribute data elements to the passenger and baggage attribute RDBMS 2633 for storage as a baggage attribute record, as illustrated in Fig. 68B. Notably, subsystem 120A (which receives RFID-tag reader input) performs a "baggage identify tagging" function, wherein each baggage attribute data element is automatically tagged with the baggage identification so that the package attribute data can be stored in the RDBMS 2633 in a way that is related in the RDBMS to other baggage articles and the corresponding passenger carrying the same on board a particular scheduled flight. As shown, the baggage screening subsystem 2691 further comprises a PFNA, MRI and QRA scanning subsystem 2660 installed slightly downstream from the x-ray scanner 2650, with an object identification and attribute acquisition subsystem 120B integrated therein, for automatically scanning each BID bar coded article of baggage prior to screening, and producing visible digital images corresponding to the interior and contents of each baggage article using either PFNA, MRI and/or QRA well known in the bagging screening arts. Such scanning subsystems 2660 can be used to detect the presence of explosive materials, biological weapons (e.g. Anthrax spores), chemical agents, and the like within articles of baggage screened by the subsystem. Baggage screening station 2691 may also include a TEDS integrated into the system.

**On Page 405, amend the first full paragraph as follows:**

As shown in ~~Fig. 69A~~ Figs. 69A1 through 69A3, the system further comprises a hand-held RFID-tag reader 2695 with a LCD panel 2695A, keypad 2695B, and a RF interface 2695C providing a wireless communication link to a mobile base station 2696, comprising an RF transmitter 2696A and server 2696B which is operably connected to the LAN in which the RDBMS 2633 is connected. The function of the hand-held RFID-tag reader 2695 is to receive instructions from the Data Processing Subsystem 2634 about the identity and attributes of a suspect passenger and/or articles of baggage, and to use the RFID-tag reader 2695 to determine exactly where the baggage resides in the event of there being a need to access the baggage article and remove it from the baggage handling system or aircraft. During operation, the hand-held RFID-tag reader 2695 generates a RF-based interrogation field which interrogates the whereabouts of a particular BID-encoded RFID-tag 2697 (on an article of baggage). This interrogation process is achieved by generating and locally broadcasting a set of RF-harmonic frequencies (from the RFID-tag reader 2697) which correspond to the natural resonant frequencies of the RF-tuned circuits used to create the BID-encoded structure underlying the RFID-tag. When the suspect baggage resides within the interrogation field of the hand-held RFID-tag reader 2695, an audible and/or visual alarm is signaled from the reader, causing the operator to take immediate action and retrieve the RFID-tag article of baggage from either the baggage handling system or a particular aircraft or other vehicle. Also, the LCD panel of the RFID-tag reader 2696 can access and display other types of attribute information maintained in the RDBMS 2633 about the suspect article of baggage.
